BETTER TOGETHER

Smarter PCV spending. More protection against RSV.

NAMIBIA

Pneumonia is a leading killer of children under five in Namibia, causing 330 deaths in 2024 according to UNICEF. Pneumococcus and respiratory syncytial virus (RSV) are leading bacterial and viral causes of childhood pneumonia respectively.

Namibia already vaccinates children against pneumococcus with pneumococcal conjugate vaccine (PCV). Now, a new maternal RSV vaccine offers the opportunity to protect babies against RSV too.

Namibia is currently exploring optimizing its PCV program by switching product or by reducing doses, both of which would generate savings to help fund this additional protection.

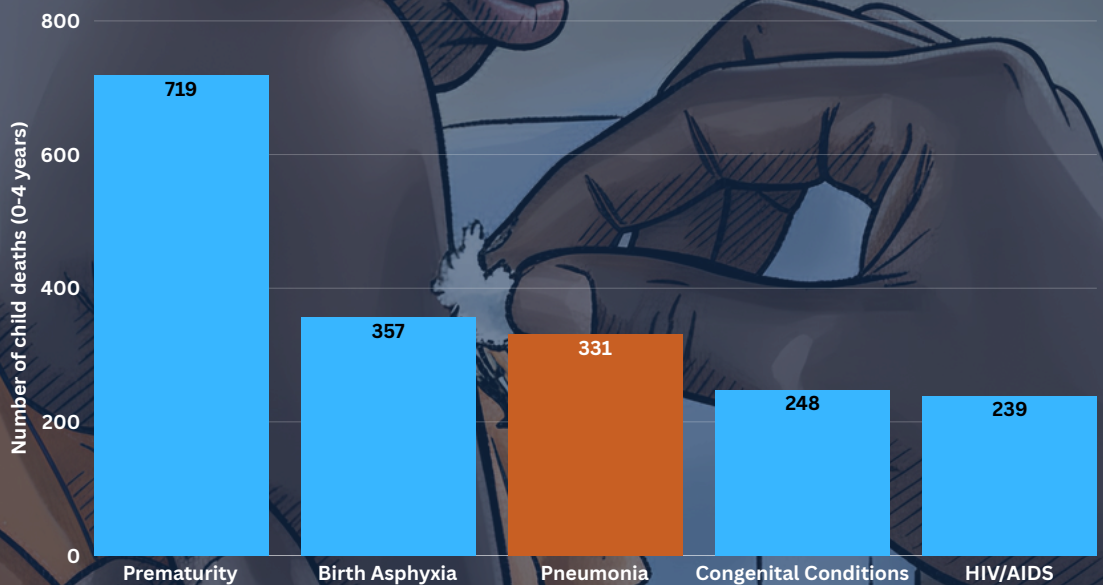

This brief uses the new PCV-OPTIMISE tool, developed at the University of Melbourne, Australia, to estimate the savings to Namibia from these PCV optimization options.

It also presents the latest estimates of Namibia's RSV burden, underscoring the case for reinvesting PCV 1+1 savings in maternal RSV vaccination.

Better together, these two vaccines will help Namibia prevent more pneumonia, reduce hospitalizations, and save more children's lives - while making existing resources go further.

PCV OPTIMIZATION SAVINGS

PCV-OPTIMISE compares the costs of Namibia's current PCV program - three doses of Prevenar 13 - between 2026 and 2030, with three optimization scenarios.

Here are the results (all numbers rounded):

1. Switching to two-doses (1+1) of Synflorix reduces costs from US$19 million to US$13 million, saving Namibia US$6 million (32%). This option requires 35% less cold-chain space.

1. Switching to three doses of Pneumosil reduces costs from US$19 million to US$7 million, saving Namibia US$12 million (63%). This option requires the same amount of cold-chain space.

3. Switching to two-doses (1+1) of Pneumosil reduces costs from US$19 million to US$5 million, saving Namibia US$14 million (74%). This option requires 35% less cold-chain space.

Estimates are conditional on Namibia being able to procure Pneumosil through UNICEF Supply Division at US$4 per-dose. As they are not eligible for Gavi support, they currently pay US$12 per Synflorix dose.

Countries planning both a PCV product and a schedule change should pursue a staged transition, with the sequence determined by national vaccine authorities based on local evidence and program readiness.

NAMIBIA

PCV AND RSV MATERNAL VACCINE

PCV and maternal RSV vaccines are better together because they strengthen protection against major bacterial and viral causes of pneumonia, especially during babies' vulnerable first six months.

Research suggests that protection against these two pathogens may be mutually reinforcing: pneumococcal vaccination has been associated with fewer RSV hospitalizations, while a French study linked RSV prevention using the antibody nirsevimab to fewer hospitalizations for invasive pneumococcal disease.

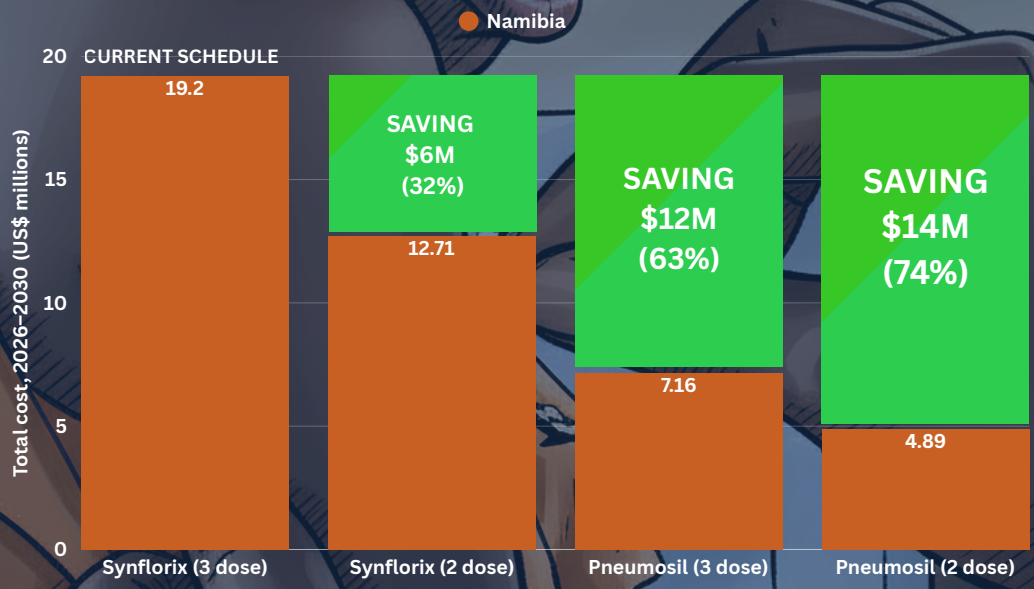

The estimated US$6 million savings from switching to two-dose Synflorix create an opportunity for Namibia to reap these gains by introducing maternal RSV vaccination.

At a price of US$3.50 per dose, these savings could purchase maternal RSV vaccine for all all 395,687 projected pregnancies in Namibia during 2026–2030, leaving approximately US$5.10 million toward delivery, wastage, and freight.

Realizing this opportunity would give Namibia a practical route to protect more children with existing resources and advance national child survival goals.

NAMIBIA

WHY IS RSV PREVENTION SO IMPORTANT FOR NAMIBIA?

Over the next decade RSV will sicken an estimated 240,000 children under five in Namibia, hospitalizing 5,900 and killing 600, absent introduction of the new prevention tools.

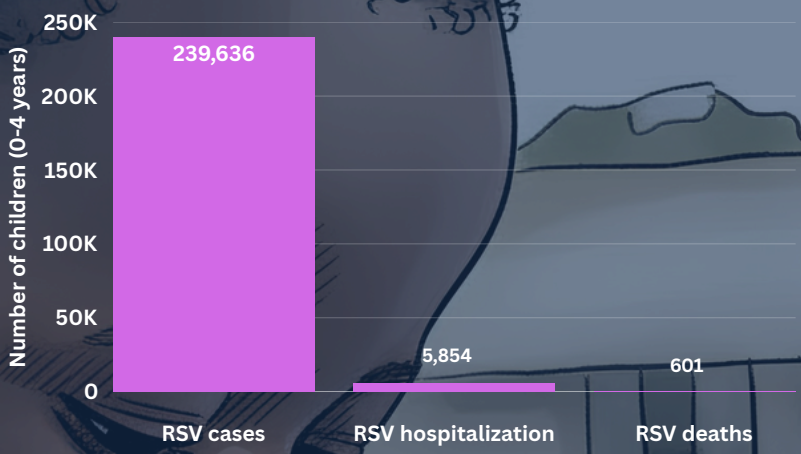

This not only places a heavy burden on families but also on the health system, as hospital wards fill with sick children during RSV season each year.

In a clinical trial, maternal RSV vaccination resulted in 70% fewer babies developing severe RSV disease during their first six months, with an exploratory analysis reported 31% fewer hospitalizations for pneumonia from any cause.

In real-world studies, maternal RSV vaccination was associated with 85% fewer RSV hospitalizations in England and 87% fewer RSV intensive care admissions among babies under six months in Argentina.

The World Health Organization recommends all countries introduce either maternal RSV vaccination, given from 28 weeks of pregnancy onwards, or a long-acting antibody for infants.
